### Memory usage and execution time Comparison

C#

```
Execution Time: 69 ms
Current process: System.Diagnostics.Process (Clock)
Physical memory usage: 44122112 bytes
Peak physical memory usage 0 bytes
```

#### **Python**

Current Usage: 0 Peak Usage: 1793

Execution Time: 0.5152420997619629 second

#### Why Python's memory usage is so low compare to C#?

The memory usage difference between Python and C# implementations stems from comparing incompatible metrics rather than actual performance. Python's tracemalloc measurement of 1,793 bytes only tracks Python object allocations, excluding interpreter overhead and system libraries, while C#'s 45MB measurement encompasses the entire process including the .NET runtime infrastructure. The .NET Common Language Runtime requires 20-30MB baseline memory for the Just-In-Time compiler, garbage collector, and runtime services before any application code executes.

#### Why C# is so fast compare to python?

The execution time difference, 69ms for C# versus 0.51 seconds for Python, occurs because C# uses Just-In-Time compilation to convert code into optimized native machine instructions that run directly on the processor, while Python interprets bytecode through a virtual machine layer that adds significant overhead. C#'s static typing enables compile-time optimizations and eliminates runtime type checks, whereas Python's dynamic typing requires constant runtime type resolution and method lookups.
